PROCESS TEMPERATURE & COMPENSATION

Temperature influences the physical properties of gases, so temperature compensation is required for a thermal sensor to accurately measure gas flow rates.

- **Standard Temperature Compensation (STC)** is used for process temperatures from 0°C to 125°C over a moderate velocity range.
- **Velocity Temperature Mapping (VTM)** is used when the process temperature and gas velocity vary widely. Multiple velocity calibrations are stored in the meter. VTM compensation is based on air; specific gas correlations are required to ensure accuracy at high temperatures.

The flow area (Fa) is the flow measurement section of the 534FTB, as shown in Parent Number table.

SPECIALTY GAS VELOCITY CALIBRATION

There are two types of gas calibration:

- **Laboratory gas calibrations** are performed with gases of high purity and are NIST traceable. Values above the calibrating facility limit are correlated up to the specified range. Customers must specify the calibration process pressure.
- **Correlation gas calibrations** are based on experimental data correlated to an Air calibration at ambient pressure and temperature. The flow element is calibrated in Air, and then an additional calibration data sheet is generated using the correlation factors. All correlation calibrations include velocity-temperature mapping.

Add $\pm 5\%$ of reading to the accuracy specification when using a correlation calibration.

For Oxygen gas, the customer is responsible for ensuring the mass flow sensor is clean of hydrocarbons and safe for Oxygen use.

ANALOG & DIGITAL INPUTS

All options include USB, RS-485 interface with ASCII text and Modbus protocols.

The 4-20mA analog outputs (AO) are used for flow rate and/or temperature, or one AO for PID flow control.

Relay outputs (DO) can be alarms, EPA zero-mid-span drift is active, or pulsed totalizer function. PID uses one 4-20mA output for the flow controller. The EPA zero-mid-span drift check requires a contact closure to start the drift check. All 4-20mA outputs are used during the Drift Check Calibration process.

EPA zero-mid-span drift check can be initiated using Digital inputs (DI), elapsed runtime automatic drift check, Modbus, or HART.

The 4-20mA input (AI) supports feedback to the device.

BASELINE FLOW RATES

Maximum flow rates are based on sensor actual velocity at standard conditions (77F, 14.69 PSIA). Up to 33% higher flow rates are possible with compressed gas applications. Provide process pressure and temperature to your Kurz representative for a detailed maximum flow rate based on your application.

F8	Option	Process Pressure
	---	Enter the Absolute Pressure (PSIA) rounded to 3 digits. For example, a process Absolute Pressure of 14.7 PSIA, round to 15.0 and enter 015; for 150 PSIA enter 150.

F9	Option	Analog and Digital Inputs/Output
	B	Standard Two 4-20mA isolated outputs
	C	Full Two 4-20mA isolated outputs, two relays, two digital inputs, one non-isolated 4-20mA input
	E	HART-1 One 4-20mA isolated output, two relays, two digital inputs, one non-isolated 4-20mA input

F10	Option	Process Temperature
	---	Enter the Absolute Temperature (°Rankin = °F + 460) rounded to 3 digits. For example, a Process Temperature of 77°F is written as 537 (77 + 460).
